Date of Deposit

I hereby certify that this correspondence is being deposited with the United States Postal Service "Express Mail Post Office to Addressee" service under 37 CFR 1.10 on the date indicated above and is addressed to the Assistant Commissioner for Patents, Washington, D.C. 20231.

Lizzy Perkins.

Signature of person mailing correspondence

Lizzy Perkins

STRUCTURED DESIGN DOCUMENTATION IMPORTER

BACKGROUND OF THE INVENTION

1. Technical Field:

[0001] The present invention is related generally to the preparation of tests in a manufacturing environment. More specifically, the present invention is directed toward the importation of testing specifications from a design specification document.

2. Description of Related Art:

[0002] The components of design documentation that are used in the specification of manufacturing requirements must be translated precisely into the applicable manufacturing processes in order to correctly implement design intent. Any errors in this regard could lead to a defective product being shipped to customers or an acceptable product inadvertently being categorized as defective.

[0003] Consider for example the specification of electrical test limits. If incorrect test limits are included in a test program and defective product inadvertently passes a test operation because of this error, a defective product is shipped to customers. This error can occur when, for whatever reason, the test engineer is not applying the correct test limits from the design documentation. Sometimes this error occurs because new design documentation has been released, and the test program has not been updated to reflect this change. Other times this error results because the test engineer incorrectly enters the limits into the test software program.

[0004] The traditional approach of translating design documentation into applicable manufacturing processes is to manually reenter design information into a medium suitable for a specific manufacturing process. Design documentation is typically in a format appropriate for users of desktop application programs such as word processors, spreadsheets, or CAD (Computer Aided Design) applications. Manufacturing information used to control a manufacturing process directly, on the other hand, is typically in a custom format suitable for a particular piece of equipment such as a software program in a test system. Sometimes a software tool is available to

electronically link subsets of the design documentation such as test limits. But in the case of manufacturing test requirements, there is currently no way to electronically import all of the relevant elements of manufacturing test requirements (including, for example, the testing method and test conditions) from a design document. Thus, it would be desirable to be able to import

5   testing specifications directly from a design document.

SUMMARY OF THE INVENTION

[0005] The present invention provides a method, computer program product, and data processing system for importing test specifications from a design document into testing software for performing testing in a manufacturing environment. A design document is written in a structured format, within a spreadsheet, word-processor document, XML file, or other document. Importer software extracts the testing information from the structured format and translates the information into a format that is readable by testing software. The translated information is then submitted to the testing software for testing the product described in the design document.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

[0007] **Figure 1** is a diagram depicting a hardware system that may be used to carry out processes of the present invention in a preferred embodiment;

[0008] **Figure 2** is a high-level flow diagram depicting the basic process followed in a preferred embodiment of the present invention;

[0009] **Figure 3** depicts an EXCEL® workbook **300** containing worksheets representing design/test specifications of a given product platform to be imported into test software in accordance with a preferred embodiment of the present invention;

[0010] **Figure 4** is flowchart representation of a process followed by an importer in accordance with a preferred embodiment of the present invention;

[0011] **Figure 5** is a diagram depicting a dialog box for entry of information identifying a product platform, product code, and test operation in accordance with a preferred embodiment of the present invention;

[0012] **Figure 6** depicts a table of test specifications as imported into a test executive and displayed through a graphical user interface (GUI) in accordance with a preferred embodiment of the present invention;

[0013] **Figure 7** provides an expanded view of a particular test in accordance with a preferred embodiment of the present invention;

[0014] **Figure 8** is a diagram depicting an expanded view showing a user-defined test specification type in accordance with a preferred embodiment of the present invention;

[0015] **Figure 9** is a diagram showing a list of fundamental characteristics imported into test executive software in accordance with a preferred embodiment of the present invention;

[0016] **Figure 10** is a diagram depicting a portion of LABVIEW test library program that may be used in accordance with a preferred embodiment of the present invention; and

[0017] **Figure 11** is a flow diagram depicting how a test program settings exporter may be used in a design and manufacturing context in accordance with a preferred embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0018] **Figure 1** is a diagram depicting a hardware system **100** that may be used to carry out processes of the present invention in a preferred embodiment. Computer **102** is in communication with and in control of a piece of testing equipment **104**, which in this case is a device for performing tests on an integrated power-supply module **106**. Power-supply module **106** is placed within a zero-insertion-force socket **108** for testing. To test power-supply module **106**, electrical signals are applied to power-supply module **106** through zero-insertion-force socket **108** under the control of computer **102**. The behavior of power supply module **106** is monitored and recorded by computer **102**, which determines whether power supply module **106** has passed the test by complying with a set of test specifications provided to computer **102**.

[0019] One of ordinary skill in the art will appreciate that hardware system **100** is paradigmatic of a large number of various types of computer-controlled tests and that the actual hardware depicted in **Figure 1** is merely a demonstration of a particular embodiment. In actuality, testing equipment **104** could be any type of computer-controlled testing equipment: electrical, chemical, mechanical, biometric, or any other computer-controlled testing equipment could be used without departing from the scope or spirit of the invention. One of ordinary skill in the art will also recognize that the term "computer" can be interpreted broadly without departing from the scope or spirit of the invention. The term "computer" should be understood in a more general sense, as a device that performs computations, rather than as a particular choice of hardware components. While a conventional personal computer or workstation (**102**) is depicted in **Figure 1**, any of a broad range of computing devices could be used in place of computer **102**, including an embedded computer or microcontroller incorporated into testing equipment **104**.

[0020] The present invention provides a method, computer program product, and data processing system for importing test specifications from a design document into testing software for performing testing in a manufacturing environment. **Figure 2** is a high-level flow diagram depicting the basic process followed in a preferred embodiment of the present invention. A design document is written in a structured format, within a spreadsheet, word-processor document, XML file, or other document (step **200**). Importer software extracts the testing information from the structured format and translates the information into a format that is

readable by testing software (step **202**). The translated information is then submitted to the testing software for testing the product described in the design document (step **204**).

[0021] In the case of a manufacturing test process, the relevant design information and testing specifications typically include, but are not limited to, the following elements:

1. Product Platform

A designer may wish to group similar products into a product platform. This information can be used to associate to a specific test function library.

2. Product Code

The product code should be visibly displayed on the operator display so the test operator can confirm the product they are testing.

3. Revision Number

The revision number can also be displayed on the operator display to confirm the current design documentation number. This is especially important in ISO auditing to allow an auditor to confirm the current revision number against the latest version.

4. Fundamental Characteristics of the Product

These are characteristics that define the overall characteristics of the product that may be useful in performing the tests. For example, a DC nominal output voltage of a power supply being tested could be used to scale the output voltage result in terms of percent from nominal if required by a particular Test Method (see 7, below).

5. Test List including sequence of tests

These are the specific tests required to test product conformity. The exact sequence may be important to ensure acceptable operation.

6. Test Name

The test name is important in order to provide a unique mapping of names in the design documentation to the test results. In this manner, follow-up data analysis can be unambiguously related to the design documentation.

7. Test Method

The test method defines the method required to perform the test as specified by the designer. This ensures that the test result has been obtained using correct procedures.

8. Test Description

The test description provides a field to elaborate the nature of the test being performed. Having this information available in the test program helps clarify the nature of the test at the test station without having to refer back to the design document.

9. Test Conditions

Test conditions specify the stimulus for performing the test, and are used by the test programmer to set the instruments to the correct conditions. Each condition should include the name, the value and units of the condition to ensure proper implementation. The Test Method itself may imply a unique condition, or one or more conditions may be specified depending on the test.

10. Test Limits

Once a measurement is taken for each test, it must be compared to limits that define conformance to specification. Test limits should also include units of measurement to ensure proper application of pass/fail status and to unambiguously report results. In general, both a minimum and maximum limit is defined.

11. Resolution of Digits (Numerical Precision)

It is important for the designer to correctly convey the required resolution with both Test Conditions and Test Limits in order to obtain the desired accuracy. This is uniquely defined in the design documentation by showing the numbers with the desired decimal point placement and trailing zeros. The resulting importer then can uncover this information through software, and apply appropriately in the test program.

[0022] In summary, the present invention provides a way to unambiguously translate deign documentation into a manufacturing test process. Among the errors that are eliminated by use of the present invention are any recurring typographical errors, or errors that occur when an incorrect design documentation version is referenced. The methodology requires a structured design documentation format and an importer that translates this information into a format suitable for use during the manufacturing/testing process. The importer is preferably in the form of a program of functional descriptive material recorded on a computer-readable medium. The functional descriptive material may include instructions, rules (such as rules of inferences), formulas, functions, queries, statements, databases (including deductive databases), or any other computer-readable data that when executed by a computer, enables the computer to act in

accordance with the processes of the present invention. Once an importer has been written and verified for correctness, it can be used to import test specifications from the structured design document. Besides eliminating mistakes, this approach also saves time. The test engineer no longer must retype the design documentation into the test program. The software importer

5   provides this function, and the tedium of typing information is eliminated.

[0023] A preferred embodiment of the present invention translates information from a design document in a structured format into a format suitable for use in a test process. It is necessary for a full understanding of the invention, therefore, to understand what is meant by a structured format. A structured format is a data format or document format that contains both data and

10   metadata. Data is simply any kind of information. Metadata is information that imposes organization, structure, or meaning on the data. Metadata is often referred to as "data about the data."

[0024] Metadata is best understood by example. In a table of data, for instance, the headings (such as column headings) and titles are metadata that impose both structure and meaning to the

15   data. For example, an airline table of departure times will likely have the headings "flight number," "origin," "destination," "departure time," and "arrival time." Those headings are metadata that serve to both organize (e.g., into columns and rows) and give meaning to the data (e.g., by distinguishing an arrival time from a departure time). Tags in a markup language, such as XML (extensible markup language) or HTML (hypertext markup language) are also metadata.

20   For example, an XML document will have tags that represent different types of data. Metadata also need not be as explicit as tags or headings. For example, a word processor or spreadsheet document into different pages representing different items of data may also be considered as including metadata, where the metadata in this case consists of page separators or page breaks.

[0025] Many different structured document formats exist in the art, and it is impossible to

25   enumerate all of the applicable formats. Moreover, it is anticipated that in the future, many new structured formats will be created. For purposes of demonstration, the structured format of a MICROSOFT EXCEL® file is used to describe a preferred embodiment of the present invention, but one of ordinary skill will recognize that any one of a number of structured formats may be used within the present invention.

Structured Document

[0026] **Figure 3** depicts an EXCEL® workbook **300** containing worksheets representing design/test specifications of a given product platform to be imported into test software in accordance with a preferred embodiment of the present invention. Each worksheet (e.g., **301**) represents a different product code of the platform. Worksheet tab names (e.g., **302**) represent product codes and the workbook as a whole (**300**) defines an entire product platform. The worksheet in this example (**301**) applies to a DC-DC converter product and contains two tables.

[0027] Table 1 (**304**) shows the fundamental characteristics of the product. A value **306** for each characteristic is provided along with a unit of measurement **308** (where applicable), a description of the characteristic **310**, and a name for the characteristic **312**.

[0028] Table 2 (**314**) contains a list of tests and all of the required information to perform each test. A name of the tested value **316** is provided along with a method number **318**, description of the test **320**, conditions under which the test will be performed **322**, and desired ranges of values (test limits) for a room ambient test **324** and hot test **326**, along with the unit of measurement for the tested value **328**.

[0029] Method number **318** refers to a paragraph number of a separate test methods document controlled by the design organization. Taken together, the documentation uniquely conveys all of the necessary information in a structured format to perform the test. Observe that there are two sets of test limits in this example, one set for a room ambient test (**324**) and one set for hot test (**326**). Each set of test limits refers to a separate test operation performed at different times in a manufacturing process. In general, more and/or different test operations may be added as required as long as the corresponding common test step information applies. When a test is to be skipped, the test limit columns are left blank to convey this information to the importing program. In the general case, the specific names used in the tables can be arbitrarily defined to suit a given product implementation.

Importer

[0030] **Figure 4** is flowchart representation of a process followed by an importer in accordance with a preferred embodiment of the present invention. Input is received from a user to identify the product platform(s), product code(s) and test operation(s) to be applied (step **400**). Test

specification data is extracted from a structured document containing the corresponding design/test specifications (step **402**). A variable list containing the values of test parameters is assembled from the extracted data (step **404**). Finally, this variable list is written into data to be used by the test program (step **406**). In a preferred embodiment, this data will be stored in a database or other file-type used by the specific test program to be used. Alternatively, this data could be stored in memory for immediate use by the program (e.g., through inter-process communication, sockets, mailboxes, or a similar process). Once the importation process is completed, the test process can be initiated to perform the tests using this same information.

[0031] **Figure 5** is a diagram depicting a dialog box **500** for entry of information identifying a product platform, product code, and test operation (step **400** in **Figure 4**) in accordance with a preferred embodiment of the present invention. The importer software application selected for this demonstration in written as an add-on to the commercially available application development environment LABVIEW (available from National Instruments, Inc. of Austin, Texas), but any software capable of performing the importing function can be used such as VISUAL BASIC® (available from Microsoft, Inc, of Redmond, Washington) or ANSI C.

[0032] The test operator (user) selects a document describing the appropriate product platform in text field **502** (the document is an EXCEL® workbook in the illustrated example), and the software populates a "Product Code" control **504** with a list of all tab names of the specified workbook. Based on a particular selection of a product code, a "Test Operation" control **506** is populated with all test operations specified for that product code. The test operator then selects one of these depending on the test operation they are to perform. After all selections are made, the test operator clicks StartLot button **508** and the software imports the documentation into the test program. This process can be further mistake-proofed by scanning in a barcode from a manufacturing ticket that contains all of the required input information.

Test Program

[0033] The test program operating software (also called a test executive) must be capable of passing the imported design documentation into applicable sections of the underlying software. In a preferred embodiment, TESTSTAND, a test executive produced by National Instruments,

5 Inc., is used to perform test sequencing and management, and LABVIEW is used for performing the specific test functions (test library functions), such as controlling instruments and making measurements. One of ordinary skill in the art will recognize that different test executive and/or test library software could be used instead without departing from the scope or spirit of the present invention.

10 [0034] **Figure 6** depicts a table of test specifications **600** as imported into a test executive and displayed through a graphical user interface (GUI) in accordance with a preferred embodiment of the present invention. The test names (**602**), test limits (**604**) with units, and test descriptions (**606**) are shown in this view. In a preferred embodiment, the tests will appear (and thus be performed) in order of their appearance in the original document.

15 [0035] **Figure 7** provides an expanded view **700** of a particular test in table **600** in accordance with a preferred embodiment of the present invention. The testing specifications are shown in a hierarchical (tree) view **701**, with a label representing the entire list of tests **702** as the root of the tree and the currently viewed test **704** displayed as a child of root label **702**. Other information fields **706** extend from the currently viewed test **704** in a similarly hierarchical manner. A list of

20 individual values **708** appears to the right of hierarchical view **701**. List **708** represents values given to an individual set of test conditions represented as label **710** in hierarchical view **701**.

[0036] The set of test specifications imported into the test executive program may include test specification types that are pre-defined by the test executive program or user-defined test specifications types. **Figure 8** is a diagram depicting an expanded view **800** showing a user-

25 defined test specification type in accordance with a preferred embodiment of the present invention. TESTSTAND software does not pre-define a test specification called "Method" (recall that "Method" in the previous examples refers to paragraph numbers in an external testing document). Therefore, a user-defined specification "Method" **802** must be defined to contain the imported method information (**804**).

[0037] In addition to information imported for each individual test, fundamental characteristics (see **304** in **Figure 3**) that define specifications that are common to all of the imported tests may also be imported. **Figure 9** is a diagram showing a list (**900**) of such fundamental characteristics imported into test executive software in accordance with a preferred embodiment of the present invention.

[0038] In a preferred embodiment, test executive software will, upon request, automatically invoke test library software perform the specified tests in accordance with the imported test specifications. **Figure 10** is a diagram depicting a portion of LABVIEW test library program that may be used in accordance with a preferred embodiment of the present invention. LABVIEW allows test programs to be written in diagram form. Diagram **1000** is a screenshot from LABVIEW showing portion of one such program in which test specifications may be imported. Box **1102** shows that the test specifications are read from a test sequence provided by the test executive.

[0039] When a particular test library test function is executed to perform a test, it uses only the information that was originally obtained from the correct version of the design documentation. The measured results are subsequently passed back to the test executive to make a pass/fail decision based on limits originally imported from the design document. In a preferred embodiment, the sequencing of tests follows exactly the sequence of the design document, according to the order in which imported data is stored for use by the text executive.

Exporter

[0040] An additional feature can be added to export test program settings back to the design document. **Figure 11** is a flow diagram depicting how a test program settings exporter may be used in a design and manufacturing context in accordance with a preferred embodiment of the present invention.

[0041] As before, a design document is written in a structured format (step **1100**). Importer software extracts the testing information from the structured format and translates the information into a format that is readable by testing software (step **1102**). The translated information is then submitted to the testing software for testing the product (step **1104**). The imported test information may be debugged and edited using test executive software in the event that the original design document contains mistakes (step **1106**). The test information, once

debugged, can then be exported (step **1108**) to produce an unofficial design document based on the test specifications actually in use (step **1110**). A designer may then review or edit this new document and release an official design document based on the modifications (step **1112**). The process may then be repeated with the new design document.

[0042] Exporting of edited test program values back into the design documentation may be desirable in a product development phase when a preliminary test requirements design document is edited at the test program level to refine the requirements. This process should be done under strict control so that the official design documentation remains under the control of the designer. By making the official design documentation file read-only, the exported test program requirements can be exported only to an unofficial file for later review/editing and ultimate official release by the designer.

[0043] It is important to note that while the present invention has been described in the context of a fully functional data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in a variety of forms of computer readable media containing functional descriptive material and that the present invention applies with equal force regardless of the particular type(s) of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disk, a hard disk drive, a RAM, CD-ROMs, DVD-ROMs, and transmission-type media, such as digital and analog communications links, wired or wireless communications links using transmission forms, such as, for example, radio-frequency and lightwave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular data processing system.

[0044] The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
